A new expression for the curvature and constraint equations (CEs) are introduced to consider the effects of the initial shape of the centerline and the thickness profile described by B-spline curves , which have been applied extensively in shape optimization , , . Following the derivation, the model is used to implement static deflection behavior and solve optimization problems to enhance performance in terms of the effective stiffness, Poisson's ratio, maximum stress, and volume, of the ...

Using Altair OptiStruct, one can optimize the composite panel design achieving significant weight savings and performance enhancements. Composite Optimization Process. The composite optimization process involves three steps: 1) ply shape optimization, 2) ply shape sizing, and 3) ply order optimization. Ply shape optimization uses a combination of topology and topography optimization methods known as composite free-size optimization.

The topic of this paper is to minimize the flexibility of a sheet with respect to its thickness and shape of boundary. These characteristics will be considered in the same algorithm, which both prevent suboptimization and mean that the user does not have to supervise the use of linked optimization tools. The refined boundary description also makes it possible to include pressure loads in this ...

Optimization techniques are applied in the design of structures in order to obtain an efficient solution in terms of weight, cost or performance. The three structural optimization types are: Sizing, Shape and Topology Optimization. The objective of a Sizing Optimization is to find the optimal thickness or cross sectional distribution of a structure.

evaluate and optimize their performance. Existing tools are usually either accurate or e cient, but not both. This paper presents a tool that can analyze airfoils in both subsonic and transonic regimes in about one hundredth of a second, and optimize airfoil shapes in a few seconds. We use camber and thickness mode shapes derived from over one thousand

Data-based Approach for Fast Airfoil Analysis and Optimization

The present optimization allows for camber and thickness variation of curved and polygonal thin airfoils with sharp leading edges. The airfoil performance is evaluated at the highest attainable lift- to-drag ratio near a moderate lift coefficient at compressible Mach numbers, as expected for Martian rotor application.
