A sequence of exercises for the isolation and characterization of invertase (E.C. 3.1.2.26) from baker's yeast obtained from a local grocery store is outlined. Because the enzyme is colorless, the use of colored markers and the sequence of purification steps are designed to "visualize" the process by which a colorless protein is selectively detected and isolated from a mixture of many different proteins.

A soluble form of invertase (β -D-fructofuranoside fructohydrolase, EC 3.2.1.26) has been purified from ripe banana fruit (*Musa cavendishii*). The enzyme has a high specific activity and an apparent MW of 220 000 daltons; it appears to be glycoprotein containing 12.5% mannose and 12% glucosamine.

Abstract. The invertase inhibitor was isolated, purified and characterized biochemically and electrophoretically from sugarbeet roots. Acid and alkaline invertase was found in roots of sugarbeet. The acid invertase activity decreased during development whereas the alkaline invertase persisted throughout the foot development.

PCR was used to isolate an invertase homolog gene from the fission yeast *Schizosaccharomyces pombe*. The cloned *inv1(+)* gene encodes a protein of 581 amino acids with 16 potential asparagine-linked glycosylation sites, and has 39% and 38% identity to the *Schwanniomyces occidentalis* and *Saccharomyces cerevisiae* SUC2 invertases.

This protein effectively inhibited the invertase activity in a dose-dependent manner. The results presented in the Lineweaver-Burk plots indicated that the invertase inhibitor displayed a mode of competitive inhibition towards the invertase tested, with a K_i of 3.82×10^{-6} mol L⁻¹. CONCLUSION: These results suggested that SPIT1 is a novel member of the ITI family in plants.
